Provably Efficient Tensor Algorithms 1/28

Tensors and algebraic structures

We consider the expression of data as indexable collections of elements and algorithms as applications of algebraic operators.

Definition (Algebraic structure)

A set of elements (type), potentially equipped with operators and identities

Examples: set, monoid, group, semiring, ring

Definition (Tensor)

A collection of elements of a single type, **T**, with some order k and dimensions (n_1, \ldots, n_k) , with elements $T_{i_1 \ldots i_k}$

Examples: scalar, vector, matrix

An algebraic structure defines summation and contraction of tensors.

Numerical tensor computations

Classical matrix-based computations over the $(+,\cdot)$ ring

• stencil computations (iterative methods for sparse linear systems)

$$\mathbf{x}^{(l)} \coloneqq \mathbf{A} \mathbf{x}^{(l-1)}$$

• dense matrix factorizations (direct solvers for dense linear systems)

$\mathbf{A}\approx\mathbf{L}\mathbf{U}\qquad\mathbf{A}\approx\mathbf{Q}\mathbf{R}\qquad\mathbf{A}\approx\mathbf{U}\mathbf{D}\mathbf{V}^{\mathsf{T}}$

• tensor contractions (perturbation theory, solvers for nonlinear systems)

$$\sum_{f} F_{f}^{a} T_{ij}^{fb} - \sum_{n} F_{i}^{n} T_{nj}^{ab} + \frac{1}{2} \sum_{e,f} V_{ef}^{ab} T_{ij}^{ef} + \frac{1}{2} \sum_{m,n} V_{ij}^{mn} T_{mn}^{ab} - \sum_{e,m} V_{ei}^{am} T_{mj}^{eb}$$

• tensor decompositions (compression)

Discrete tensor algorithms

Alternative algebraic structures expand potential of tensor computations

- graph algorithms via tropical (geodetic) semiring (min, +)
 - single-source shortest-paths via Bellman-Ford (stencil-like)
 - all-pairs shortest-paths (APSP) via Floyd-Warshall (LU-like)
 - APSP via path doubling (matrix-multiplication-like)
 - betweenness centrality
 - hypergraphs are representable by tensors
- recursion via higher order tensors
 - prefix sum, scan
 - FFT or other butterfly networks
 - bitonic sort
- particle methods
 - direct particle-particle force evaluation
 - particle-mesh (PM, P3M, SPME, PIC)

Cost model for parallel algorithms

Given a schedule that specifies all work and communication tasks on p processors, we consider the following costs, measured along dependent sequences of tasks (as in $\alpha - \beta$, BSP, and LogGP models).

Definition (*F* – computation cost)

Number of operations performed

Definition (Q - vertical communication cost)

Amount of data moved between memory and cache

Definition (W - horizontal communication cost)

Amount of data moved between processors

Definition (S - synchronization cost)

Number of distinct messages sent between processors

Edgar Solomonik

Bilinear algorithms

A bilinear algorithm Λ is defined by three matrices, $\Lambda = (\mathbf{F}^{(A)}, \mathbf{F}^{(B)}, \mathbf{F}^{(C)})$ Given input vectors **a** and **b**, it computes vector,

$$\mathbf{c} = \mathbf{F}^{(\mathbf{C})}[(\mathbf{F}^{(\mathbf{A})\mathsf{T}}\mathbf{a}) \circ (\mathbf{F}^{(\mathbf{B})\mathsf{T}}\mathbf{b})]$$

where \circ is the Hadamard (pointwise) product

$$\begin{bmatrix} \mathbf{C} \end{bmatrix} = \begin{bmatrix} \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \end{bmatrix} \begin{bmatrix} \begin{pmatrix} \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x}$$

- the number of columns in the three matrices is equal and is the bilinear algorithm rank, denoted rank(Λ)
- the number of rows in each matrix corresponds to the number of inputs (dimensions of **a** and **b**) and outputs (dimension of **c**)

Bilinear algorithm expansion

A bilinear algorithm $\Lambda = (\mathbf{F}^{(\mathbf{A})}, \mathbf{F}^{(\mathbf{B})}, \mathbf{F}^{(\mathbf{C})})$ has expansion bound $\mathcal{E}_{\Lambda} : \mathbb{N}^3 \to \mathbb{N}$, if for all projection matrices \mathbf{P} ,

$$\begin{bmatrix} \mathbf{c} \end{bmatrix} = \begin{bmatrix} \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf$$

 $\Lambda_{\rm sub} = (\mathbf{F}^{(\mathbf{A})}\mathbf{P}, \mathbf{F}^{(\mathbf{B})}\mathbf{P}, \mathbf{F}^{(\mathbf{C})}\mathbf{P})$

has rank bounded by $\mathcal{E}_{\Lambda},$

$$\mathsf{rank}(\Lambda_{\mathrm{sub}}) \leq \mathcal{E}_{\Lambda}\left(\mathsf{rank}(\mathbf{F^{(A)}P}),\mathsf{rank}(\mathbf{F^{(B)}P}),\mathsf{rank}(\mathbf{F^{(C)}P})\right)$$

Communication lower bounds

Consider any algorithm $\Lambda = (\mathbf{F}^{(\mathbf{A})}, \mathbf{F}^{(\mathbf{B})}, \mathbf{F}^{(\mathbf{C})})$ and expansion bound \mathcal{E}_{Λ} . For a cache size H, Λ requires total vertical communication cost,

$$Q \geq \left[2H rac{\mathsf{rank}(\Lambda)}{\mathcal{E}^{\max}_{\Lambda}(H)}
ight]$$

where $\mathcal{E}^{\max}_{\Lambda}(H) := \max_{c^{(A)}+c^{(B)}+c^{(C)}=3H} \mathcal{E}_{\Lambda}(c^{(A)}, c^{(B)}, c^{(C)}).$ Given *p* processors, Λ requires horizontal communication cost,

$$W \ge \min_{\substack{\mathcal{E}_{\Lambda}\left(c^{(A)} + \frac{r^{(A)}}{p}, c^{(B)} + \frac{r^{(B)}}{p}, c^{(B)} + \frac{r^{(C)}}{p}\right) \ge \frac{\operatorname{rank}(\Lambda)}{p}} \left[c^{(A)} + c^{(B)} + c^{(C)} \right]$$

where $r^{(A)}$, $r^{(B)}$, and $r^{(C)}$ are the number of rows in $\mathbf{F}^{(A)}$, $\mathbf{F}^{(B)}$, and $\mathbf{F}^{(C)}$, respectively.

Dependency interval expansion

Consider a bilinear algorithm that computes a set of multiplications V with a partial ordering, we denote a dependency interval between $a, b \in V$ as

$$[a, b] = \{a, b\} \cup \{c : a < c < b, c \in V\}$$

If there exists $\{v_1, \ldots, v_n\} \in V$ with $v_i < v_{i+1}$ and $|[v_{i+1}, v_{i+k}]| = \Theta(k^d)$ for all $k \in \mathbb{N}$, then $F \cdot S^{d-1} = \Omega(n^d)$

where F is the computation cost and S is the synchronization cost

Further, if the algorithm has bilinear expansion \mathcal{E} , satisfying $\mathcal{E}^{\max}(H) = \Omega(H^{\frac{d}{d-1}})$, then

$$W \cdot S^{d-2} = \Omega(n^{d-1})$$

Example: diamond DAG

For the $n \times n$ diamond DAG (d = 2),

$$F \cdot S^{d-1} = F \cdot S = \Omega((n/b)b^2) \cdot \Omega(n/b) = \Omega(n^2)$$
$$W \cdot S^{d-2} = W = \Omega((n/b)b) = \Omega(n)$$

idea of $F \cdot S$ tradeoff goes back to Papadimitriou and Ullman, 1987

Edgar Solomonik

Tradeoffs involving synchronization

For triangular solve with an $n \times n$ matrix

$$F_{\mathrm{TRSV}} \cdot S_{\mathrm{TRSV}} = \Omega\left(n^2\right)$$

For Cholesky of an $n \times n$ matrix

$$F_{\mathrm{CHOL}} \cdot S_{\mathrm{CHOL}}^2 = \Omega\left(n^3\right) \qquad W_{\mathrm{CHOL}} \cdot S_{\mathrm{CHOL}} = \Omega\left(n^2\right)$$

For computing s applications of a $(2m+1)^d$ -point stencil

$$F_{\mathrm{St}} \cdot S_{\mathrm{St}}^{d} = \Omega\left(m^{2d} \cdot s^{d+1}
ight) \qquad W_{\mathrm{St}} \cdot S_{\mathrm{St}}^{d-1} = \Omega\left(m^{d} \cdot s^{d}
ight)$$

Communication-optimal dense matrix algorithms

For any $c \in [1, p^{1/3}]$, use cn^2/p memory per processor and obtain

$$W_{\rm DMF} = O(n^2/\sqrt{cp}), \qquad S_{\rm DMF} = O(\sqrt{cp})$$

- LU with pairwise pivoting extended to tournament pivoting
- QR with Givens rotations extended to Householder transformations
- full-to-banded reduction for symmetric eigenvalue problem
- successive band reduction for symmetric eigenvalue problem

Parallel algorithms for the symmetric eigenvalue problem

Direct full-to-band reduction with $W = O(n^2/\sqrt{cp})$ communication

Successive band reduction with $W, Q = O(n^2 \log p / \sqrt{cp})$ communication

Edgar Solomonik

Communication-efficient stencil computations

Iterative s-step stencil computations

- previous work: in-time blocking (matrix powers kernel)
 - lowers synchronization cost by factor of b
 - lowers vertical communication cost by up to a factor of $b^{1/d}$
 - increases horizontal communication cost by an additive factor of $O(sb^{d-1})$, as dictated by the lower bound $W_{\text{St}} \cdot S_{\text{St}}^{d-1} = \Omega(s^d)$
- new 'block-cyclic' algorithm, in-time blocking executed bulk synchronously
 - lowers vertical communication cost by factor of $b^{1/d}$
 - maintains minimal horizontal communication cost
 - increases synchronization cost
- alternatives are both optimal in different lower bound regimes

Illustration of import region of the matrix-powers kernel

Scalable sparse matrix multiplication

Multiplication of a sparse matrix by a dense matrix

- key primitive with many applications
 - iterative solvers
 - tensor computations (MP3 or coupled cluster with localized orbitals)
 - graph algorithms (Bellman-Ford, APSP, betweenness centrality)
- new algorithms and analysis
 - communication-efficient 3D partitioning
 - lower bounds based on worst-case fill structure
 - extension to tensor contractions and implementation

Exploiting symmetry in tensors

Tensor symmetry (e.g. $A_{ij} = A_{ji}$) permits savings in memory and cost

- for order *d* tensor, *d*! less memory
- matrix-vector multiplication

$$c_i = \sum_j A_{ij} b_j = \sum_j A_{ij} (b_i + b_j) - \bigg(\sum_j A_{ij}\bigg) b_i$$

rank-2 vector outer product

$$C_{ij} = a_i b_j + a_j b_i = (a_i + a_j)(b_i + b_j) - a_i b_i - a_j b_j$$

squaring a symmetric matrix

$$C_{ij} = \sum_{k} A_{ik}A_{kj} = \sum_{k} (A_{ik} + A_{kj} + A_{ij})^2 - \dots$$

• for order ω contraction, ω ! less multiplications (lower bilinear rank)

Edgar Solomonik

Symmetry preserving algorithms

By exploiting symmetry, we can reduce the number of multiplications at the cost of more additions

- algorithms generalize to most antisymmetric tensor contractions
- for Hermitian tensors, multiplications cost 3X more than additions
 - BLAS routines: hemm and her2k as well as LAPACK routines like hetrd (tridiagonal reduction) may be done with 25% fewer operations
- achieves $(2/3)n^3$ bilinear rank for squaring a nonsymmetric matrix, assuming elementwise commutativity
- can be nested for partially symmetric contractions
 - reduction in multiplications implies reduction in nested calls to contractions
 - yields significant reductions in overall cost

Horizontal communication cost of symmetry preserving algorithms

For contraction of order s + v tensor with order v + t tensor

- Υ is the nonsymmetric contraction algorithm
- Ψ is the best previously known algorithm
- Φ is the symmetry preserving algorithm

Asymptotic communication lower bounds based on bilinear expansion

(*H*-cache size, p-#processors, *n*-dimension):

5	t	V	Fγ	Fψ	Fφ	$Q_{\Upsilon,\Psi}$	Q_{Φ}	Wγ	W_{Ψ}	W_{Φ}

- parallelization via MPI+OpenMP(+CUDA)

Jacobi iteration example code snippet

```
void Jacobi(Matrix<> A, Vector<> b, int n){
   Matrix<> R(A);
   R["ii"] = 0.0;
   Vector<> x(n), d(n), r(n);
   Function<> inv([](double & d){ return 1./d; });
   d["i"] = inv(A["ii"]); // set d to inverse of diagonal of A
   do {
      x["i"] = d["i"]*(b["i"]-R["ij"]*x["j"]);
      r["i"] = b["i"]-A["ij"]*x["j"]; // compute residual
   } while (r.norm2() > 1.E-6); // check for convergence
}
```

Tensor algebra as a programming abstraction

Cyclops Tensor Framework

- contraction/summation/functions of tensors
- distributed symmetric-packed/sparse storage via cyclic layout
- parallelization via MPI+OpenMP(+CUDA)

Møller-Plesset perturbation theory (MP3) code snippet

```
Z["abij"] += Fab["af"]*T["fbij"];
Z["abij"] -= Fij["ni"]*T["abnj"];
Z["abij"] += 0.5*Vabcd["abef"]*T["efij"];
Z["abij"] += 0.5*Vijkl["mnij"]*T["abmn"];
Z["abij"] -= Vaibj["amei"]*T["ebmj"];
```

Betweenness centrality

Betweenness centrality code snippet, for k of n nodes

```
void btwn_central(Matrix<int> A, Matrix<path> P, int n, int k){
   Monoid<path> mon(...,
```

```
[](path a, path b){
    if (a.w<b.w) return a;
    else if (b.w<a.w) return b;
    else return path(a.w, a.m+b.m);
}, ...);</pre>
```

```
Matrix<path> Q(n,k,mon); // shortest path matrix
Q["ij"] = P["ij"];
```

```
Function<int,path> append([](int w, path p){
            return path(w+p.w, p.m);
        }; );
```

```
for (int i=0; i<n; i++)
Q["ij"] = append(A["ik"],Q["kj"]);</pre>
```

Performance of CTF for dense computations

CTF is highly tuned for massively-parallel machines

- virtualized multidimensional processor grids
- topology-aware mapping and collective communication
- performance-model-driven decomposition done at runtime
- optimized redistribution kernels for tensor transposition

Performance of CTF for sparse computations

All-pairs shortest-paths based on path doubling with sparsification

Edgar Solomonik

Provably Efficient Tensor Algorithms 23/28

Application to Coupled Cluster

Coupled cluster methods

- approximate solution to manybody time-independent Schrödinger equation via set of nonlinear equations
- use 2*r*-order tensor to represent *r*-electron correlation
 - measure excitation energy of r electrons to r virtual orbitals
 - each possible set of transitions (intermediate states) becomes a product of tensors
 - factorization of this set of multilinear tensor products transforms equations to bilinear tensor contractions
- systematically improvable, CCSD, CCSDT, CCSDTQ (r = 1, 2, 3)
- partial antisymmetries in tensors as a consequence of electron interchangeability
- symmetry preserving algorithms can reduce cost of CCSD by about 1.3, CCSDT by about 2.1

CCSD using CTF

```

Other electronic structure codes using CTF include QChem (via Libtensor)

Comparison with NWChem

NWChem is the most commonly-used distributed-memory quantum chemistry method suite

- provides CCSD and CCSDT
- uses Global Arrays a Partitioned Global Address Space (PGAS) backend for tensor contractions
- derives equations via Tensor Contraction Engine (TCE)

Coupled Cluster on IBM BlueGene/Q

Future work

- further work sparse and symmetric tensor computations
 - bridging the gap between abstractions and application performance
 - bilinear algorithm complexity fast matrix multiplication
- tensor decompositions
 - communication-efficient parallel algorithms and lower bounds
 - symmetry-preserving tensor decomposition and DMRG algorithms
 - programming abstractions for dense and sparse tensors
- sets of tensor operations
 - most algorithms correspond to multiple dependent tensors operations
 - communication cost analysis for sets of contractions
 - scheduling, blocking, and decomposition of multiple tensor operations
 - higher-level programming abstractions
- application-driven development
 - tensor decompositions, sparsity, symmetry all motivated by electronic structure applications

Symmetry preserving algorithm vs Strassen's algorithm

Nesting of bilinear algorithms

Given two bilinear algorithms:

$$\begin{split} &\Lambda_1 = &(\textbf{F}_1^{(\textbf{A})}, \textbf{F}_1^{(\textbf{B})}, \textbf{F}_1^{(\textbf{C})}) \\ &\Lambda_2 = &(\textbf{F}_2^{(\textbf{A})}, \textbf{F}_2^{(\textbf{B})}, \textbf{F}_2^{(\textbf{C})}) \end{split}$$

We can nest them by computing their tensor product

$$\begin{split} & \Lambda_1 \otimes \Lambda_2 \coloneqq (\textbf{F}_1^{(\textbf{A})} \otimes \textbf{F}_2^{(\textbf{A})}, \textbf{F}_1^{(\textbf{B})} \otimes \textbf{F}_2^{(\textbf{B})}, \textbf{F}_1^{(\textbf{C})} \otimes \textbf{F}_2^{(\textbf{C})}) \\ & \mathsf{rank}(\Lambda_1 \otimes \Lambda_2) = \mathsf{rank}(\Lambda_1) \cdot \mathsf{rank}(\Lambda_2) \end{split}$$

Block-cyclic algorithm for s-step methods

For s-steps of a $(2m+1)^d$ -point stencil with block-size of $H^{1/d}/m$,

$$W_{\mathrm{Kr}} = O\left(rac{msn^d}{H^{1/d}p}
ight) \quad S_{\mathrm{Kr}} = O(sn^d/(pH)) \quad Q_{\mathrm{Kr}} = O\left(rac{msn^d}{H^{1/d}p}
ight)$$

which are good when $H = \Theta(n^d/p)$, so the algorithm is useful when the cache size is a bit smaller than n^d/p

$$\begin{aligned} \tau_{ij}^{ab} &= t_{ij}^{ab} + \frac{1}{2} P_b^a P_j^i t_i^a t_j^b, \\ \tilde{F}_e^m &= f_e^m + \sum_{fn} v_{ef}^{mn} t_n^f, \\ \tilde{T}_e^{ab} &= (t_e - t_e) \epsilon_e^{ab} - \sum_{fn} \tilde{T}_e^m - t_n^{-1} \sum_{fn} m_{en} t_n^f, \end{aligned}$$

$$\tilde{F}_{e}^{a} = (1 - \delta_{ae})f_{e}^{a} - \sum_{m} \tilde{F}_{e}^{m}t_{m}^{a} - \frac{1}{2}\sum_{mnf} v_{ef}^{mn}t_{mn}^{af} + \sum_{fn} v_{ef}^{an}t_{n}^{f},$$

$$\tilde{F}_{i}^{m} = (1 - \delta_{mi})f_{i}^{m} + \sum_{e} \tilde{F}_{e}^{m}t_{i}^{e} + \frac{1}{2}\sum_{nef} v_{ef}^{mn}t_{in}^{ef} + \sum_{fn} v_{if}^{mn}t_{n}^{f},$$

Our CCSD factorization

$$\begin{split} \tilde{W}_{ei}^{mn} &= v_{ei}^{mn} + \sum_{f} v_{ef}^{mn} t_{i}^{f}, \\ \tilde{W}_{ij}^{mn} &= v_{ij}^{mn} + P_{j}^{i} \sum_{e} v_{ie}^{mn} t_{i}^{e} + \frac{1}{2} \sum_{ef} v_{ef}^{mn} \tau_{ij}^{ef}, \\ \tilde{W}_{ie}^{am} &= v_{ie}^{am} - \sum_{n} \tilde{W}_{ei}^{mn} t_{n}^{a} + \sum_{f} v_{ef}^{ma} t_{i}^{f} + \frac{1}{2} \sum_{nf} v_{ef}^{mn} t_{in}^{af}, \\ \tilde{W}_{ij}^{am} &= v_{ij}^{am} + P_{j}^{i} \sum_{e} v_{ie}^{am} t_{j}^{e} + \frac{1}{2} \sum_{ef} v_{ef}^{am} \tau_{ij}^{ef}, \\ z_{i}^{a} &= f_{i}^{a} - \sum_{m} \tilde{F}_{i}^{m} t_{m}^{a} + \sum_{e} f_{e}^{a} t_{i}^{e} + \sum_{em} v_{ei}^{ma} t_{m}^{e} + \sum_{em} v_{im}^{ae} \tilde{F}_{e}^{m} + \frac{1}{2} \sum_{efm} v_{ef}^{am} \tau_{im}^{ef} \\ &- \frac{1}{2} \sum_{emn} \tilde{W}_{ei}^{mn} t_{mn}^{ea}, \\ z_{ij}^{ab} &= v_{ij}^{ab} + P_{j}^{i} \sum_{e} v_{ie}^{ab} t_{j}^{e} + P_{b}^{a} P_{j}^{i} \sum_{me} \tilde{W}_{ie}^{am} t_{mj}^{eb} - P_{b}^{a} \sum_{m} \tilde{W}_{ij}^{am} t_{m}^{b} \\ &+ P_{b}^{a} \sum_{e} \tilde{F}_{e}^{a} t_{ij}^{eb} - P_{j}^{i} \sum_{m} \tilde{F}_{m}^{im} t_{mj}^{ab} + \frac{1}{2} \sum_{ef} v_{ef}^{ab} \tau_{ij}^{ef} + \frac{1}{2} \sum_{mn} \tilde{W}_{ij}^{mn} \tau_{mn}^{ab}, \end{split}$$

Stability of symmetry preserving algorithms

Performance breakdown on BG/Q

Performance data for a CCSD iteration with 200 electrons and 1000 orbitals on 4096 nodes of Mira 4 processes per node, 16 threads per process Total time: 18 mins *v*-orbitals, *o*-electrons

kernel	% of time	complexity	architectural bounds
DGEMM	45%	$O(v^4 o^2 / p)$	flops/mem bandwidth
broadcasts	20%	$O(v^4 o^2/p\sqrt{M})$	multicast bandwidth
prefix sum	10%	<i>O</i> (<i>p</i>)	allreduce bandwidth
data packing	7%	$O(v^2 o^2 / p)$	integer ops
all-to-all-v	7%	$O(v^2 o^2 / p)$	bisection bandwidth
tensor folding	4%	$O(v^2 o^2 / p)$	memory bandwidth

Tiskin's path doubling algorithm

Tiskin gives a way to do path-doubling in $F = O(n^3/p)$ operations. We can partition each \mathbf{A}^k by path size (number of edges)

$$\mathbf{A}^k = \mathbf{I} \oplus \mathbf{A}^k(1) \oplus \mathbf{A}^k(2) \oplus \ldots \oplus \mathbf{A}^k(k)$$

where each $\mathbf{A}^{k}(I)$ contains the shortest paths of up to $k \ge I$ edges, which have exactly I edges. We can see that

$$\mathbf{A}^{\prime}(l) \leq \mathbf{A}^{\prime+1}(l) \leq \ldots \leq \mathbf{A}^{n}(l) = \mathbf{A}^{*}(l),$$

in particular $\mathbf{A}^*(I)$ corresponds to a sparse subset of $\mathbf{A}^I(I)$. The algorithm works by picking $I \in [k/2, k]$ and computing

$$(\mathbf{I} \oplus \mathbf{A})^{3k/2} \leq (\mathbf{I} \oplus \mathbf{A}^k(I)) \otimes \mathbf{A}^k,$$

which finds all paths of size up to 3k/2 by taking all paths of size exactly $l \ge k/2$ followed by all paths of size up to k.
