Towards an algebraic formalism for scalable numerical algorithms

# Communication-synchronization wall

To analyze parallel algorithms, we consider costs along the critical path of the execution  ${\rm schedule}^1$ 

- F computation cost
- W horizontal communication cost
- S synchronization cost

We can show a commonality between

- Cholesky of an  $n \times n$  matrix and
- *n* steps of a 9-pt stencil:

$$W \cdot S = \Omega(n^2)$$

regardless of #processors<sup>1</sup>

## <sup>1</sup>E.S., E. Carson, N. Knight, J. Demmel, TOPC 2016

Householder Symposium XX

## Tradeoffs in the diamond DAG

Computation vs synchronization tradeoff for the  $n \times n$  diamond DAG,<sup>1</sup>

$$F \cdot S = \Omega(n^2)$$

In this DAG, vertices denote scalar computations in an algorithm

#### <sup>1</sup>C.H. Papadimitriou, J.D. Ullman, SIAM JC, 1987

Householder Symposium XX

Towards an algebraic formalism for scalable numerical algorithms

# Scheduling tradeoffs of path-expander graphs

## Definition (( $\epsilon, \sigma$ )-path-expander)

Graph G = (V, E) is a  $(\epsilon, \sigma)$ -**path-expander** if there exists a path  $(u_1, \ldots u_n) \subset V$ , such that the dependency interval  $[u_i, u_{i+b}]_G$  for each i, b has size  $\Theta(\sigma(b))$  and a minimum cut of size  $\Omega(\epsilon(b))$ .

#### Theorem (Path-expander communication lower bound)

Any parallel schedule of an algorithm with a  $(\epsilon, \sigma)$ -path-expander dependency graph about a path of length n and some  $b \in [1, n]$  incurs computation (F), communication (W), and synchronization (S) costs:

$$F = \Omega\left(\sigma(b) \cdot n/b\right), \quad W = \Omega\left(\epsilon(b) \cdot n/b\right), \quad S = \Omega\left(n/b\right).$$

#### Corollary

If  $\sigma(b) = b^d$  and  $\epsilon(b) = b^{d-1}$ , the above theorem yields,

$$F \cdot S^{d-1} = \Omega(n^d), \quad W \cdot S^{d-2} = \Omega(n^{d-1}).$$

Householder Symposium XX

## Synchronization-communication wall in iterative methods

The theorem can be applied to sparse iterative methods on regular grids. For computing s applications of a  $(2m + 1)^d$ -point stencil,

$$F_{\mathsf{St}} \cdot S^d_{\mathsf{St}} = \Omega\left(m^{2d} \cdot s^{d+1}\right), \qquad W_{\mathsf{St}} \cdot S^{d-1}_{\mathsf{St}} = \Omega\left(m^d \cdot s^d\right)$$

while *s*-step methods reduce synchronization, for large *s* they require asymptotically more communication.

The lower bound is attained by *s*-step methods when *s* approaches the dimension of each processor's local subgrid.

## A more scalable algorithm for TRSM

For Cholesky factorization with p processors, parallel schedules can attain

$$F = O(n^3/p), \quad W = O(n^2/p^\delta), \quad S = O(p^\delta)$$

for any  $\delta = [1/2, 2/3]$ . Achieving similar costs for LU, QR, and the symmetric eigenvalue problem requires some algorithmic tweaks.

triangular solve	square TRSM $\sqrt{1}$	rectangular TRSM $\sqrt{2}$
LU with pivoting	pairwise pivoting $\sqrt{3}$	tournament pivoting $\checkmark^4$
QR factorization	Givens on square $\sqrt{3}$	Householder on rect. $\sqrt{5}$
SVD	singular values only $\sqrt{5}$	singular vectors X

 $\checkmark$  means costs attained (synchronization within polylogarithmic factors). Ongoing work on QR with column pivoting

## New algorithms can circumvent lower bounds

For TRSM, we can achieve a lower synchronization/communication cost by performing triangular inversion on diagonal blocks

- decreases synchronization cost by  $O(p^{2/3})$  on p processors with respect to known algorithms
- optimal communication for any number of right-hand sides
- MS thesis work by Tobias Wicky<sup>1</sup>

<sup>1</sup>T. Wicky, E.S., T. Hoefler, IPDPS 2017

## Improving scalability for iterative methods

Randomized-projection methods have potential to significantly improve scalability over iterative Krylov subspace methods

- key idea: replace sparse mat-vecs with sparse mat-muls
- define  $n \times (k + 10)$  Gaussian random matrix  $oldsymbol{X}$
- AX gives a good representation of the kernel of A
- accuracy can be improved exponentially with  $q^1$

$$(\mathbf{A}\mathbf{A}^T)^q \mathbf{A}\mathbf{X}$$

 $\bullet\,$  many related results with high potential for efficiency (e.g. randomized column pivoting for QR  $^2)$ 

 $^1\text{N}.$  Halko, P.G. Martinsson, J.A. Tropp, SIAM Review 2011  $^2\text{P.G}.$  Martinsson, G. Quintana Orti, N. Heavner. R. van de Geijn, SIAM 2017

Need algorithms and methods that are more parallelizable rather than parallel schedules of existing algorithms.

## How can we formally define an algorithm?

Formally defining a space of algorithms enables systematic exploration.

Definition (Bilinear algorithms (V. Pan, 1984))

A bilinear algorithm  $\Lambda = (F^{(A)}, F^{(B)}, F^{(C)})$  computes

$$\boldsymbol{c} = \boldsymbol{F}^{(\boldsymbol{C})}[(\boldsymbol{F}^{(\boldsymbol{A})\top}\boldsymbol{a}) \circ (\boldsymbol{F}^{(\boldsymbol{B})\top}\boldsymbol{b})],$$

where  $\boldsymbol{a}$  and  $\boldsymbol{b}$  are inputs and  $\circ$  is the Hadamard (pointwise) product.

$$\begin{bmatrix} \mathbf{c} \end{bmatrix} = \begin{bmatrix} \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf{x} \\ \mathbf{x} & \mathbf$$

10/27

## Bilinear algorithms as tensor factorizations

A bilinear algorithm corresponds to a CP tensor decomposition

$$c_{i} = \sum_{r=1}^{R} F_{ir}^{(C)} \left( \sum_{j} F_{jr}^{(A)} a_{j} \right) \left( \sum_{k} F_{kr}^{(B)} b_{k} \right)$$
$$= \sum_{j} \sum_{k} \left( \sum_{r=1}^{R} F_{ir}^{(C)} F_{jr}^{(A)} F_{kr}^{(B)} \right) a_{j} b_{k}$$
$$= \sum_{j} \sum_{k} T_{ijk} a_{j} b_{k} \quad \text{where} \quad T_{ijk} = \sum_{r=1}^{R} F_{ir}^{(C)} F_{jr}^{(A)} F_{kr}^{(B)}$$

For multiplication of  $n \times n$  matrices,

- **T** is  $n^2 \times n^2 \times n^2$
- classical algorithm has rank  $R = n^3$
- Strassen's algorithm has rank  $R \approx n^{\log_2(7)}$

11/27

## Expansion in bilinear algorithms

The communication complexity of a bilinear algorithm depends on the amount of data needed to compute subsets of the bilinear products.

Definition (Bilinear subalgorithm)

Given  $\Lambda = (F^{(A)}, F^{(B)}, F^{(C)})$ ,  $\Lambda_{sub} \subseteq \Lambda$  if  $\exists$  projection matrix P, so

$$\Lambda_{\rm sub} = (\boldsymbol{F}^{(\boldsymbol{A})}\boldsymbol{P}, \boldsymbol{F}^{(\boldsymbol{B})}\boldsymbol{P}, \boldsymbol{F}^{(\boldsymbol{C})}\boldsymbol{P}).$$

The projection matrix extracts #cols(P) columns of each matrix.

## Definition (Bilinear algorithm expansion)

A bilinear algorithm  $\Lambda$  has expansion bound  $\mathcal{E}_\Lambda:\mathbb{N}^3\to\mathbb{N},$  if for all

$$\Lambda_{\mathrm{sub}} \coloneqq (\boldsymbol{F}_{\mathrm{sub}}^{(\boldsymbol{A})}, \boldsymbol{F}_{\mathrm{sub}}^{(\boldsymbol{B})}, \boldsymbol{F}_{\mathrm{sub}}^{(\boldsymbol{C})}) \subseteq \Lambda$$

we have  $\mathsf{rank}(\Lambda_{\mathrm{sub}}) \leq \mathcal{E}_{\Lambda}\left(\mathsf{rank}(\boldsymbol{F}_{\mathrm{sub}}^{(\boldsymbol{A})}),\mathsf{rank}(\boldsymbol{F}_{\mathrm{sub}}^{(\boldsymbol{B})}),\mathsf{rank}(\boldsymbol{F}_{\mathrm{sub}}^{(\boldsymbol{C})})\right)$ 

For matrix mult., Loomis-Whitney inequality  $o \mathcal{E}_{\mathsf{MM}}(x,y,z) = \sqrt{xyz}$ 

## Bilinear algorithms for symmetric tensor contractions

- A tensor  $\boldsymbol{T} \in \mathbb{R}^{n_1 imes \cdots imes n_d}$  has
  - order *d* (i.e. *d* modes / indices)
  - dimensions *n*-by-···-by-*n*
  - elements  $\mathbf{T}_{i_1...i_d} = \mathbf{T}_{i}$  where  $i \in \{1, \ldots, n\}^d$

We say a tensor is symmetric if for any  $j, k \in \{1, \ldots, n\}$ 

$$\boldsymbol{T}_{\boldsymbol{i}_1\ldots\boldsymbol{i}_j\ldots\boldsymbol{i}_k\ldots\boldsymbol{i}_d}=\boldsymbol{T}_{\boldsymbol{i}_1\ldots\boldsymbol{i}_k\ldots\boldsymbol{i}_j\ldots\boldsymbol{i}_d}$$

A tensor is partially-symmetric if such index interchanges are restricted to be within subsets of  $\{1, \ldots, n\}$ , e.g.

$$\boldsymbol{T}_{kl}^{ij} = \boldsymbol{T}_{kl}^{ji} = \boldsymbol{T}_{lk}^{ji} = \boldsymbol{T}_{lk}^{ij}$$

For any  $s, t, v \in \{0, 1, \ldots\}$ , a tensor contraction is

$$\forall \mathbf{i} \in \{1, \dots, n\}^{s}, \mathbf{j} \in \{1, \dots, n\}^{t}, \quad \mathbf{C}_{ij} = \sum_{\mathbf{k} \in \{1, \dots, n\}^{v}} \mathbf{A}_{ik} \mathbf{B}_{kj}$$

13/27

## Symmetric matrix times vector

Lets consider the simplest tensor contraction with symmetry

- let  $\boldsymbol{A}$  be an *n*-by-*n* symmetric matrix ( $\boldsymbol{A}_{ij} = \boldsymbol{A}_{ji}$ )
- the symmetry is not preserved in matrix-vector multiplication

$$c = A \cdot b$$

$$c_i = \sum_{j=1}^{n} \underbrace{A_{ij} \cdot b_j}_{\text{nonsymmetric}}$$

• generally  $n^2$  additions and  $n^2$  multiplications are performed • we can perform only  $\binom{n+1}{2}$  multiplications using<sup>1</sup>

$$\boldsymbol{c}_{i} = \sum_{j=1, j \neq i}^{n} \underbrace{\boldsymbol{A}_{ij} \cdot (\boldsymbol{b}_{i} + \boldsymbol{b}_{j})}_{\text{symmetric}} + \underbrace{\left(\boldsymbol{A}_{ii} - \sum_{j=1, j \neq i}^{n} \boldsymbol{A}_{ij}\right) \cdot \boldsymbol{b}_{i}}_{\text{low-order}}$$

Householder Symposium XX

## Symmetrized outer product

Consider a rank-2 outer product of vectors  $\boldsymbol{a}$  and  $\boldsymbol{b}$  of length n into symmetric matrix  $\boldsymbol{C}$ 

usually computed via the  $n^2$  multiplications and  $n^2$  additions new algorithm requires  $\binom{n+1}{2}$  multiplications

15/27

## Symmetrized matrix multiplication

For symmetric matrices **A** and **B**, compute

$$\boldsymbol{C}_{ij} = \sum_{k=1}^{n} \Big( \underbrace{\boldsymbol{A}_{ik} \cdot \boldsymbol{B}_{kj}}_{\text{nonsymmetric}} + \underbrace{\boldsymbol{A}_{jk} \cdot \boldsymbol{B}_{ki}}_{\text{permutation}} \Big)$$

New algorithm requires  $\binom{n+2}{3}$  multiplications rather than  $n^3$ 

$$C_{ij} = \sum_{k \neq i,j} \underbrace{\left(\mathbf{A}_{ij} + \mathbf{A}_{ik} + \mathbf{A}_{jk}\right) \cdot \left(\mathbf{B}_{ij} + \mathbf{B}_{kj} + \mathbf{B}_{ki}\right)}_{\mathbf{Z}_{ijk} - \text{symmetric}} - \underbrace{\sum_{k \neq i}^{n} \mathbf{A}_{ik} \cdot \mathbf{B}_{ik}}_{\mathbf{W}_{i} - \text{low-order}} - \underbrace{\sum_{k \neq j}^{n} \mathbf{A}_{jk} \cdot \mathbf{B}_{jk}}_{\mathbf{W}_{j} - \text{low-order}} + \underbrace{\frac{1}{n-2} \left( (2-n)\mathbf{A}_{ij} - \mathbf{A}_{i}^{(1)} - \mathbf{A}_{j}^{(1)} \right) \cdot \left( (n-2)\mathbf{B}_{ij} + \mathbf{B}_{i}^{(1)} + \mathbf{B}_{j}^{(1)} \right)}_{\mathbf{U}_{ij} - \text{low-order}} + \underbrace{\frac{1}{n-2} \left( \mathbf{A}_{i}^{(1)} + \mathbf{A}_{j}^{(1)} \right) \cdot \left( \mathbf{B}_{i}^{(1)} + \mathbf{B}_{j}^{(1)} \right)}_{\mathbf{V}_{ij} - \text{low-order}} + \underbrace{\frac{1}{n-2} \left( \mathbf{A}_{i}^{(1)} - \sum_{k \neq i}^{n} \mathbf{A}_{ki} \right)}_{\mathbf{V}_{ij} - \text{low-order}} \text{ and } \mathbf{B}_{i}^{(1)} = \left( \mathbf{B}_{ii} - \sum_{k \neq i}^{n} \mathbf{B}_{ki} \right).$$

16/27

Generally consider any symmetric tensor contraction for  $s, t, v \in \{0, 1, \ldots\}$ 

$$\forall \mathbf{i} \in \{1, \dots, n\}^{s}, \mathbf{j} \in \{1, \dots, n\}^{t}, \mathbf{C}_{ij} = \sum_{\mathbf{k} \in \{1, \dots, n\}^{v}} \mathbf{A}_{ik} \mathbf{B}_{kj} + \text{permutations}$$

- best previous algorithms used roughly  $\binom{n}{s}\binom{n}{t}\binom{n}{v}$  multiplications, new algorithm requires roughly  $\binom{n}{s+t+v}$  multiplications
- these are bilinear algorithms and correspond to a CP decomposition of the symmetric contraction tensor that defines the problem
- analysis of bilinear expansion gives us communication lower bounds
  - surprising negative result when s + t + v ≥ 4 and s ≠ t ≠ v asymptotically more communication necessary for new algorithm!
- algorithm can be nested in the case of partially-symmetric contractions, leads to a reduction in cost – manyfold cost improvements in some high-order quantum chemistry methods

## Analysis of bilinear algorithms

There are a few very fundamental bilinear problems

- matrix multiplication
- symmetric tensor contractions
- convolution

The algebraic formulation enables systematic derivation and analysis

- direct proof of correctness
- CP decomposition can be computed numerically to find algorithms
- numerical stability easy to infer<sup>1</sup>
- communication lower bounds via bilinear expansion<sup>2</sup>

Some problems are multilinear or correspond to chains of bilinear algorithms, can we provide useful algebraic formulations for these problems and the space of algorithms?

<sup>2</sup>E.S., J. Demmel, T. Hoefler, 2015

Householder Symposium XX

<sup>&</sup>lt;sup>1</sup>A.R. Benson, G. Ballard, ACM SIGPLAN 2015

## A more complicated case: HSS matrices

Hierarchically-semi-separable (HSS) matrices have the structure

# HSS matrices algebraically

There are a few different ways to think about HSS matrices

- geometrically (FMM) as trees, mat-vecs do up-sweep and down-sweep
- algebraically as a telescoping block-sparse matrix factorization<sup>1</sup>

• algebraically as a dense tensor factorization like

$$\boldsymbol{U}_{ijk}^{(3)}(\boldsymbol{U}_{jk}^{(2)}(\boldsymbol{U}_{k}^{(1)}\boldsymbol{B}^{(0)}\boldsymbol{V}_{c}^{(1)}) + \delta_{k}^{c}\boldsymbol{B}_{c}^{(1)})\boldsymbol{V}_{bc}^{(2)}) + \delta_{jk}^{bc}\boldsymbol{B}_{bc}^{(2)})\boldsymbol{V}_{abc}^{(3)}$$

where summations are implicit (Einstein notation) and  $\delta$  is an identity • is this representation only a theoretical curiosity?

<sup>1</sup>P.G. Martinsson, SIAM Journal on Matrix Analysis and Applications, 2011 Householder Symposium XX Towards an algebraic formalism for scalable numerical algorithms 20/27

## A stand-alone library for petascale tensor computations

Cyclops Tensor Framework (CTF)<sup>1</sup>

• distributed-memory symmetric/sparse tensors as C++ objects

```
Matrix<int> A(n, n, AS|SP, World(MPI_COMM_WORLD));
Tensor<float> T(order, is_sparse, dims, syms, ring, world);
T.read(...); T.write(...); T.slice(...); T.permute(...);
```

• parallel contraction/summation of tensors

```
Z["abij"] += V["ijab"];
B["ai"] = A["aiai"];
T["abij"] = T["abij"]*D["abij"];
W["mnij"] += 0.5*W["mnef"]*T["efij"];
Z["abij"] -= R["mnje"]*T3["abeimn"];
M["ij"] += Function<>([](double x){ return 1/x; })(v["j"]);
```

• development (1500 commits) since 2011, open source since 2013

## Coupled cluster: an initial application driver

CCSD contractions from Aquarius (lead by Devin Matthews) https://github.com/devinamatthews/aquarius

```
FMI["mi"] += 0.5*WMNEF["mnef"]*T2["efin"];
WMNIJ["mnij"] += 0.5*WMNEF["mnef"]*T2["efij"];
FAE["ae"] -= 0.5*WMNEF["mnef"]*T2["afmn"];
WAMEI["amei"] -= 0.5*WMNEF["mnef"]*T2["afin"];
Z2["abij"] = WMNEF["ijab"];
Z2["abij"] += FAE["af"]*T2["fbij"];
Z2["abij"] -= FMI["ni"]*T2["abnj"];
Z2["abij"] += 0.5*WABEF["abef"]*T2["efij"];
Z2["abij"] += 0.5*WMNIJ["mnij"]*T2["abmn"];
Z2["abij"] -= WAMEI["amei"]*T2["ebmj"];
```

CTF is used within Aquarius, QChem, VASP, and Psi4

## Performance of CTF for coupled cluster

CCSD up to 55 (50) water molecules with cc-pVDZ CCSDT up to 10 water molecules with cc-pVDZ

compares well to NWChem (up to 10x speed-ups for CCSDT)

## Sparse MP3 code

# Strong and weak scaling of sparse MP3 code, with (1) dense V and T (2) sparse V and dense T (3) sparse V and T

# CTF for betweenness centrality

Betweenness centrality is a measure of the importance of vertices in the shortest paths of a graph

- can be computed using sparse matrix multiplication (SpGEMM) with operations on special monoids
- CTF handles this in similar ways to CombBLAS

Friendster has 66 million vertices and 1.8 billion edges (results on Blue Waters, Cray XE6)

 $\label{eq:communication} Communication + synchronization \mbox{ are a fundamental bottleneck in many algorithms}$ 

- scalability of standard algorithms for dense LU, QR, SVD and sparse iterative methods is well understood theoretically
- much to explore in practice, important algorithms not yet implemented
- lower bounds motivate more radical algorithmic changes

Bilinear algorithms and tensor factorization representations

- provide an analytical tool for deriving lower-bounds
- demonstrate insights on communication of new algorithms for symmetric tensor contractions
- enable succinct algebraic description in native dimensionality
- allow for effective parallel implementation based on high-level specification (Cyclops Tensor Framework)
